In the model, the input is transformed into a feature vector and then passed through the classification layer to determine the class of the image. The model is trained using a large dataset of labeled images.

The model architecture consists of several layers, including convolutional layers for feature extraction and fully connected layers for classification. The convolutional layers use kernels to extract features from the input image, and the fully connected layers combine these features to make a final prediction.

The model is evaluated on a test set of images, and the accuracy is reported as the percentage of correctly classified images. The model performs well on this task, achieving an accuracy of 95% on the test set.

In conclusion, the model is a powerful tool for image classification, and it has many potential applications in fields such as autonomous driving, medical imaging, and security.
